Introduction

The honeybee *Apis mellifera* Linnaeus, 1758 has a wide distribution across various climatic conditions. The species is subdivided into more than 30 subspecies recognized by morphological and genetic methods, ten of which are native to Europe [1]. The subspecies or geographic races are restricted in their distribution to specific geographic areas. Moreover, subspecies encompass a diverse array of ecotypes and breeding lines, demonstrating a notable diversity and their capacity to adapt to regional climate conditions, local vegetation, as well as resist pests and pathogens [2, 3]. Estonia is within the distribution area of the European dark honeybee (*A. m. mellifera*), although other subspecies have been imported by humans over the years. Despite their mating independence, both managed and feral honeybee colonies are significantly impacted by human influence.

The use of morphological, genetic and ecological data has allowed the identification of major evolutionary lineages, often associated with specific geographic regions along their natural areas of repartition in Europe, the Middle East, Western Asia and the African continent [4-8]. Three of these lineages are originally present in Europe: lineage A (the African lineage), spread through part of the Iberian Peninsula; C, widespread in southern and eastern Europe and M, found in the British Isles, north continental Europe, the Ural and some areas in Central Asia [9, 10].

The mitochondrial DNA (mtDNA) has been successfully used as a method to measure the genetic diversity and disentangle the evolutionary history and classification of *A. mellifera* [11, 12]. The mtDNA is commonly employed in phylogeography and genetic research because it exhibits no recombination, has a comparatively rapid evolutionary rate, a preserved genomic structure, and inheritance exclusively from one parent, which allows the clear tracing of lineages over generations [13, 14]. In particular, the intergenic non-coding region located between the cytochrome oxidase I (COX1) and cytochrome oxidase II (COX2) genes, known as ‘COI-COII intergenic region’, has been widely used in honeybee genetic studies (e.g., [4, 11, 15-17]). In addition to several point mutations, the COI-COII intergenic region has size variation due to the presence, absence or repetition of P and Q units. The P units has about 67 nt (P_0) or 54 nt (P) due to a 13-nt internal deletion, while the Q element has about 200 nt. The presence and number of these P and Q units is used to distinguish African (A) and European (C and M) lineages: the C lineage lacks any P units and has one Q element; the A lineage has either P_0 or P

units and one or two Q units and the M lineage has only P units and one to three Q elements [9, 10, 18].

The unique mtDNA sequences (known as haplotypes) obtained from honeybee samples has been used to identify their subspecies: A haplotypes occur in *A. m. iberiensis*, M haplotypes define *A. m. mellifera*, C1 classify *A. m. ligustica* and C2 *A. m. carnica* [1, 4, 5]. Previous works in Europe showed that A haplotypes are mostly restricted to Iberian peninsula, M haplotypes in central and northern Europe and C lineages in southern Europe, from Italy to Turkey [2]. These studies have also found evidence of human-mediated introgression at the lineage level in many European regions. The data is consistent with the fact that most beekeepers use preferentially the Italian *A. m. ligustica*, and the Carniolan *A. m. carnica* subspecies in their apiaries. For instance, studies in Belgium, Denmark, France, Germany, Poland, Sweden, and the UK, where only M lineages are native, revealed frequent introgression of C and O lineages [2]. The C branch (*A. m. ligustica*, *A. m. carnica*, *A. m. cecropia*) has spread from the Balkan and Italian Peninsulas to the northeastern coasts of the Mediterranean Sea and Central Europe. These introgressions result from the practice of long-distance translocation of subspecies for yield improvement and docility. Despite a centuries-long tradition of beekeeping and constant human interference, subspecies' specific genetic footprints are still preserved in some parts of Europe [4,33] but they are in a constant threat of hybridization, introgression and admixture which are detected in almost all analysed populations. Therefore, there is a growing interest to monitor the genetic integrity of the European *A. mellifera* subspecies that could be threatened by the human-mediated dispersion of non-native populations and lines.

The aim of this work was to perform a comprehensive genetic assessment of the genetic diversity present in Estonian honeybee populations. The analysis of mtDNA allowed the identification of the most widely circulating lineages among beekeepers. The new data can contribute to the implementation of conservation projects and to better understand the hybridization between subspecies.

Methodology

Sampling

A total of 156 honeybees were collected from 35 stationary apiaries in mainland Estonia and Muhu island during July 2023. Workers and drones were collected from 78 colonies, representing 154 samples. Two colonies were sampled only for workers, as drones were not found. Samples were collected from 13 counties in Estonia, the number of samples collected per county varied from 4 to 43 (Table 1). The number of samples collected per apiary varied from two to ten. The bees were stored in a solution of 70% ethanol until being processed in the laboratory. The DNA was extracted from the thoracic muscle mass obtained after opening the thorax with a sterilized scalpel. The DNA was extracted using the InviSorb® Spin Tissue Mini Kit (Invitek Molecular GmbH, Germany), according to the manufacturer's instructions. The extracted DNA was stored at -20 °C for further analyses.

Table 1. Distribution of honeybee samples collected per county in Estonia.

County	Nº of samples
Tartu county	43
Harju county	22
Pärnu county	17
Võru county	14
Lääne-Viru county	14
Saare county	10
Jõgeva county	10
Ida-Viru county	6
Viljandi county	4
Valga county	4
Rapla county	4
Lääne county	4
Järva county	4

Amplification of the COI-COII intergenic region

The intergenic non-coding region of the mitochondrial DNA located between the cytochrome oxidase I (COX1) and cytochrome oxidase II (COX2) genes was selected for sequencing due to its wide use in honeybee genetic studies (Figure 1). The region is historically known as 'COI-COII intergenic region'. This section of the mtDNA was amplified by Polymerase Chain Reaction (PCR) using the following PCR primers previously described [4]:

BeeCOI3278F (COI_Seq-F): 5'- ACCACCTCTAGATCATTACACATT -3'

BeeCOII4113R (COII_Seq-R): 5'- AGGATGGAACTGTTCATGAATGAA -3'

The PCR amplifications were performed on a SimpliAmp™ Thermal Cycler (Applied Biosystems, USA) in a 10 µL reaction mix containing 5 µL of Multiplex PCR Master Mix (Qiagen, Germany), 1 µL of primer mix (2 µM each), 2 µL of DNase, RNase and protease-free water and 2 µL of extracted DNA. The thermocycling conditions were: initial step at 95 °C for 15 min; 35 cycles at 94 °C for 30 s, 55 °C for 1 min 30 s, 72 °C for 1 min; with a final extension step at 72 °C for 10 min. The amplicons were separated by electrophoresis on a 2% agarose gel containing 1 X SYBR Safe DNA Gel Stain (Invitrogen, USA) at 120 V during 45 min and the fragments were visualized under UV light in a Dual LED Blue/White Light Transilluminator (Invitrogen).

Figure 1. Schematic representation of the *Apis mellifera* mitochondrial DNA from the reference genome with accession number NC_001566.1. The COI-COII intergenic region is highlighted by a green box. The PCR primers used to amplify the COI-COII intergenic region are indicated. The intergenic region of the reference genome includes a single Q element, typical of the mitochondrial lineage C.

Sequencing of the COI-COII intergenic region

Amplified products (5 µL) were purified with ExoSAP-IT® Express (USB, Affymetrix, USA) according to the manufacturer's recommendations. Sequencing of purified samples (2.5 µL) was performed as follows: 10 µL reactions were prepared by combining 0.8 µL of Big Dye® Terminator v3.1 Cycle Sequencing Kit (Applied Biosystems) with 0.8 µL of 10 µM primer, 1 µL of BigDye® Terminator v1.1 & v3.1 5X Sequencing Buffer and water DNase, RNase-free (Gibco, USA). Thermal cycler conditions were: 96°C for 2 min, 35 cycles at

96°C for 30 s, 50°C for 15 s and 60°C for 4 min and one final hold at 60°C for 10 min. Sequencing reaction products were purified using Sephadex™ G-50 Fine DNA Grade columns (GE Healthcare, United Kingdom) according to the manufacturer's recommendations. Purified samples were added to 12 µL Hi-Di™ formamide (Life Technologies, USA). Sequencing was performed in a Genetic Analyzer 3130xl sequencer (Applied Biosystems), according to the manufacturer's recommendations. Sequence analysis was performed using Sequencing Analysis software v6.0 (Applied Biosystems). The assembly of the resulting electropherograms was performed using Geneious Prime® 2022.1.1 (<https://www.geneious.com>). The final assemble was manually inspected to correct possible misalignments.

Identification of mitochondrial lineages

The curated mtDNA sequences were aligned using the Muscle 3.8.425 [19] running in the Geneious Prime® software. The alignments were used to identify the sequences with extra copies of the two types of repeated, non-coding sequences, named P and Q. The variation in the number of P and Q elements allowed the classification of samples into the main C, M and A evolutionary lineages. The haplotype of each sample was identified using as reference the curated dataset with 934 full and verified COI-COII intergenic region sequences provided by Alburaki et al. [4]. A local database with the 934 sequences was built in the Geneious Prime® software and used for blast searches with the *blastn* algorithm under default score values. The final list of blast results was ordered by the % of identical sites and the haplotype of the query sample was obtained from the haplotype of the sequence with the highest value for the % of identical sites. Standard measures of genetic diversity were obtained using DNAsp 6.12.03 [20].

Phylogenetic analyses

Phylogenies were built using the multiple sequence alignment with 156 COI-COII intergenic region sequences representing the mtDNA region from positions 3,339 to 4,063 of the reference *A. mellifera* mitochondrial genome (NC_001566.1). The extra segment with ~250 bp only found in 14 individuals was removed from the alignment prior to the phylogenetic analyses. The median-joining network [21] was calculated using the Network V10.1.0.0 software (<http://www.fluxus-engineering.com>) using default parameters. The maximum likelihood (ML) phylogenetic tree was built with PhyML 3.0 [22], implemented in the ATGC bioinformatics platform (<http://www.atgc-montpellier.fr>). The HKY85 +I substitution model of protein evolution was selected with the Smart Model

Selection (SMS) v2.0 method implemented in PhyML [23], under the BIC (Bayesian Information Criterion). The branch support was evaluated with 100 bootstraps. The resulting phylogenetic tree was edited with FigTree v1.4.3 (<http://tree.bio.ed.ac.uk/software/figtree>).

Results

Main honeybee evolutionary lineages

The PCR amplification of the mtDNA COI-COII intergenic region using the PCR primers described in Figure 1 revealed two different product sizes (Figure 2). The sequencing of the PCR products showed that the longest amplicon had the PQQ or P_0 QQ structure whereas the shortest amplicon had the Q structure.

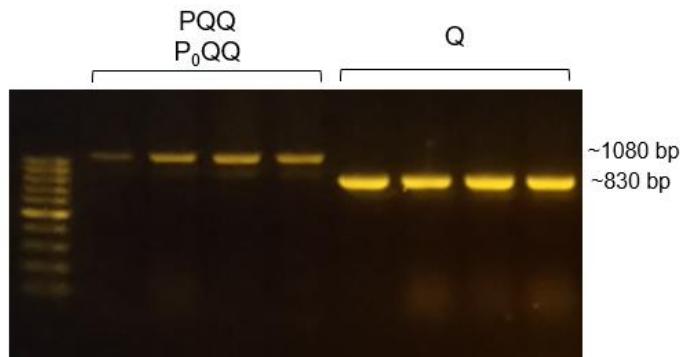

Figure 2. Electrophoretic separation of the COI-COII intergenic region amplified by PCR. The two main types of structure of the COI-COII intergenic region are shown (PQQ/ P_0 QQ and Q).

The alignment of all honeybee mtDNA sequences revealed 14 cases with an insertion of around 250 nt in relation to the reference *A. mellifera* mitochondrial genome (Figure 3). Two samples (SCK040121 and SCK040122) have the structure P_0 QQ (1%) with a P element with no deletions and two copies of the Q element (Table 2). This structure is typical of the African mitochondrial lineage A. The remaining 12 samples (8%) have the structure PQQ, with a P element including a deletion of 13 nt. This structure is common in the western and northern European lineage M.

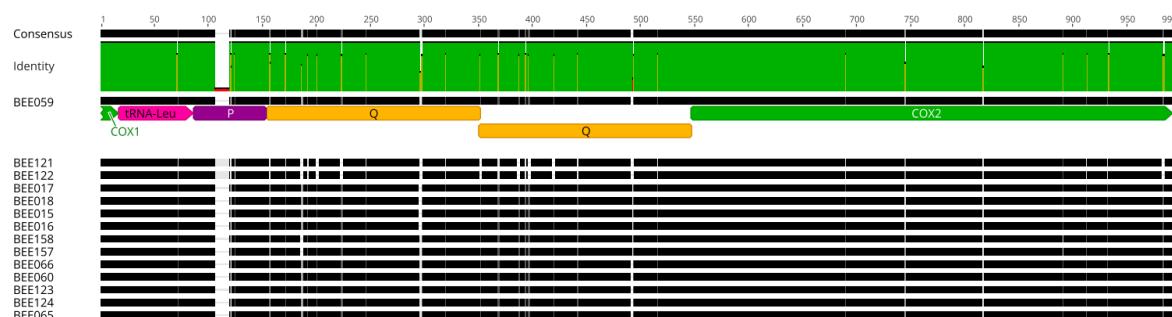

Figure 3. Multiple sequence alignment of the 14 samples with the PQQ and P_0 QQ structure in the COI-COII intergenic region.

The remaining 142 sequences (91%) have a single copy of the Q element (Table 2), typical of the southern and eastern European lineage C, as observed in the *Apis mellifera* reference genome (Figure 1).

Table 2. Classification of Estonian bee samples according to the COI-COII genetic structure and evolutionary lineage.

COI-COII genetic structure	Lineage	n	%
Q	C	142	91%
PQQ	M	12	8%
P ₀ QQ	A	2	1%
Total		156	

Mitochondrial DNA haplotypes

The 156 samples were classified into 11 haplotypes using blast searches against the curated dataset of mtDNA sequences: C1a, C2c, C2d, C2e, C2j, C2s, C2w, M4, M4j, M4na and A2g (Table 3 and Supplementary Table S1).

Table 3. Classification of Estonian bee samples according to the mitochondrial DNA haplotype and subspecies.

COI-COII genetic structure	Lineage	Haplotype	Subspecies	n	%
Q	C	C1a	<i>Apis mellifera ligustica</i>	86	55.1%
		C2c		10	6.4%
		C2d		27	17.3%
		C2e		8	5.1%
		C2j		2	1.3%
		C2s		8	5.1%
		C2w		1	0.6%
PQQ	M	M4	<i>Apis mellifera mellifera</i>	2	1.3%
		M4j		6	3.8%
		M4na		4	2.6%
P0QQ	A	A2g	<i>Apis mellifera iberiensis</i>	2	1.3%

The most common haplotype was C1a (55.1%), which characterizes the *A. m. ligustica* subspecies. This haplotype was found in 25 apiaries across Estonia (Supplementary Table S2). In addition to C1a, only haplotype C2d reached a relevant distribution (17.3%). The other haplotypes from the C lineage had a distribution of 6.4% (C2c) or lower. The haplotypes of the C2 type characterize the *A. m. carnica* subspecies. When

combined, C2 haplotypes comprise 35.9% of Estonian samples (Table 3). The haplotypes characterizing the *A. m. mellifera* subspecies (M4, M4j and M4na) represent 7.7% of the samples (Table 3) and were all collected in three apiaries (Harju County, Tartu maakond and Järva maakond). The single haplotype from the *A. m. iberiensis* subspecies (A2g) was found in a colony from the Jõgeva maakond, corresponding to only 1.3% of the samples.

Despite the smaller number of samples, *A. m. carnica* showed a higher genetic diversity than *A. m. ligustica* (Table 4). The presence of six haplotypes in *A. m. carnica* and only two in *A. m. ligustica* explains the higher diversity values in *A. m. carnica*. The genetic diversity of the three *A. m. mellifera* haplotypes is comparable to that of *A. m. carnica* (Table 4).

Table 4. Diversity measures for the *Apis mellifera* subspecies observed in Estonia based on the COI-COII intergenic region.

Lineage	Subspecies	n	Nº of polymorphic sites	Nº of haplotypes	Haplotype diversity	Nucleotide diversity	Average nº of nucleotide differences
C	<i>A. m. ligustica</i>	86	1	2	0.243	0.00034	0.243
	<i>A. m. carnica</i>	56	8	6	0.608	0.00181	1.308
M	<i>A. m. mellifera</i>	12	3	3	0.667	0.00184	1.333
A	<i>A. m. iberiensis</i>	2	0	1	0	0	0
	Complete dataset	156	19	11	0.646	0.00386	2.781

Phylogenetic analyses

The phylogenetic network of mtDNA haplotypes revealed three clearly distinct clusters of haplotypes separated by eight mutations: *A. m. mellifera*, *A. m. iberiensis* and *A. m. ligustica + A. m. carnica* (Figure 4). The difference among the three clusters is compatible with the existence of difference subspecies in *A. mellifera*. However, the separation of *A. m. ligustica* and *A. m. carnica* is not evident in the Estonian samples. Haplotypes C2c and C1a are just one mutation apart. The C2 haplotypes form a starlike pattern expanding from C2d, which is possible one of the ancestral haplotypes in this cluster. In fact, samples classified as C2d were found to have two haplotypes separated by one mutation at the centre of the network, in line with its ancestral state. Similarly, C1a samples revealed two haplotypes in the median-joining network (Figure 4). In both cases,

it is possible that some of the samples could be further classified into new haplotypes. It is also by this reason that the network shows 13 haplotypes instead of the 11 haplotypes identified by blast analyses (Table 3). The three *A. m. mellifera* haplotypes (M4, M4j and M4na) are separated by at least three mutations suggesting they diverge already some time ago.

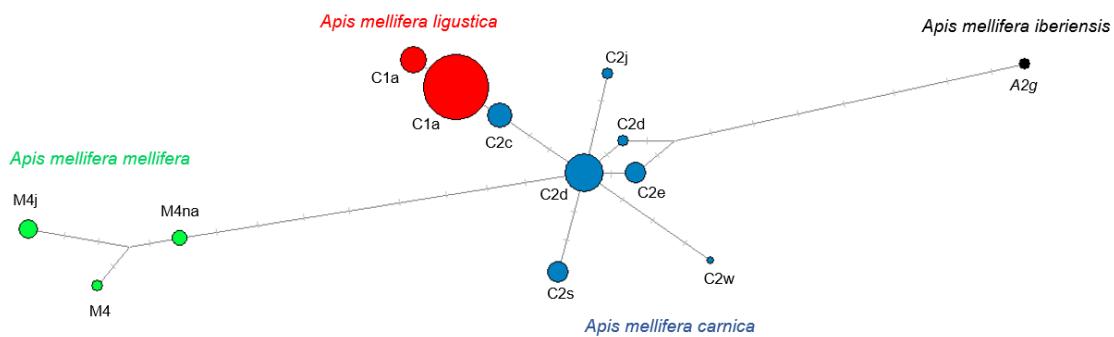

Figure 4. Median-joining network built with the alignment of 156 COI-COII intergenic region sequences of Estonian honeybees. The area of the circles is proportional to the frequency of sequences. Haplotypes are identified and coloured according to the *A. mellifera* subspecies.

The maximum likelihood (ML) phylogenetic tree supported the median-joining network analysis by separating all samples according to the haplotype classification (Figure 5). The *A. m. ligustica* and *A. m. carnica* samples cluster together, but with no overlap of haplotypes between both groups. The *A. m. mellifera* and *A. m. iberiensis* haplotypes form a separated cluster, although *A. m. iberiensis* branches out from *A. m. carnica*.

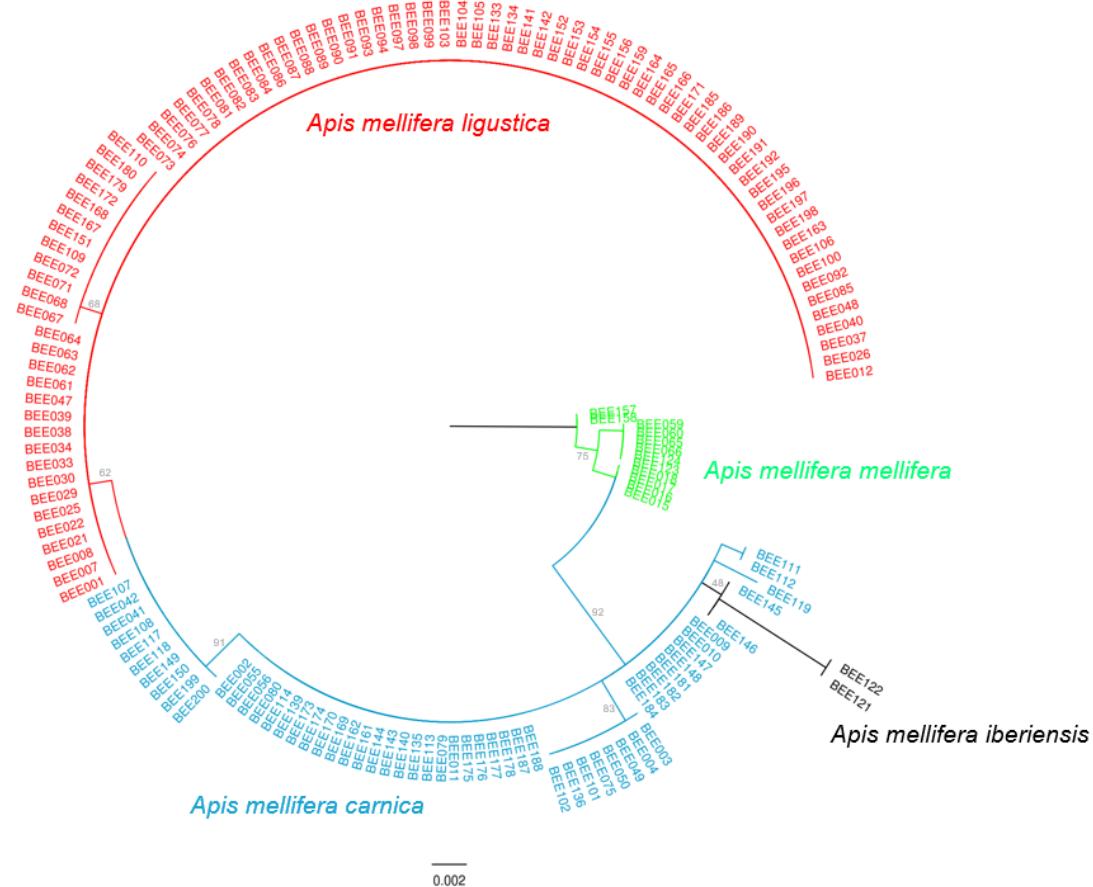

Figure 5. Maximum likelihood (ML) phylogenetic tree built with the alignment of 156 COI-COII intergenic region sequences of Estonian honeybees. The branch support was estimated with 100 bootstraps. The scale bar indicates substitutions per site.

Beekeepers' classifications

The genetic analyses revealed six cases of workers and drones from the same colony with different mtDNA sequences (Table 5). Although one should expect equal mtDNA sequences due to their descent from the same female, it is possible the occurrence of *de novo* mutations through the multiple mtDNA replications in the development of an organism. The cases of workers and drones diverging by just a few mutations (one or even two) could be explained by such process. However, the cases with three and five mutations are unlikely to have occurred *de novo* in an individual. It is possible that drones from different colonies were sampled or that some misclassification of samples has occurred.

Table 5. List of workers and drone samples from the same colony showing different mtDNA sequences for the COI-COII intergenic region with ~755 nt.

Samples from the same colony with different mtDNA sequence	Number of nt differences	% identical sites
SCK040001 vs SCK040002	3	99.6
SCK040011 vs SCK040012	3	99.6
SCK040075 vs SCK040076	5	99.3
SCK040135 vs SCK040136	2	99.7
SCK040151 vs SCK040152	1	99.9
SCK040171 vs SCK040172	1	99.9

The genetic classification of subspecies using the COI-COII intergenic region not always matched the subspecies reported by the beekeepers (Table 6). It should be noted that the mtDNA lineage may not always reflect the morphology of the bee, particularly if recent crosses between individuals of different lineages may have occurred. The most common discordance between the mtDNA and the beekeeper's classifications regards *A. m. ligustica* and *A. m. carnica*. Half the samples reported as *A. m. carnica* by beekeepers were classified as *A. m. ligustica* by the mtDNA analysis, and the opposite scenario occurred in 28% of the cases. The genetic proximity between these two subspecies, as noticed in the phylogenetic analyses (Figures 4 and 5), may explain the difficulty in separating both subspecies. In any case, 66% of *A. m. ligustica* samples identified by beekeepers were supported by the mtDNA data (Table 6). The two samples of *A. m. iberiensis* detected using mtDNA have been reported as *A. m. ligustica* by the beekeeper. There was a concordance for 60% of the cases between the beekeeper and mtDNA classification for *A. m. mellifera*. The 12 cases of bees reported as Buckfast have a mtDNA haplotype typical of *A. m. carnica*.

Table 6. Comparison of the honeybee subspecies classification according to beekeepers and the mitochondrial DNA haplotypes.

Subspecies reported by beekeeper	n	Subspecies according to mtDNA haplotypes	n	%
<i>Apis mellifera ligustica</i>	97	<i>A. m. ligustica</i>	64	66%
		<i>A. m. carnica</i>	27	28%
		<i>A. m. mellifera</i>	4	4%
		<i>A. m. iberiensis</i>	2	2%
<i>Apis mellifera carnica</i>	40	<i>A. m. ligustica</i>	20	50%
		<i>A. m. carnica</i>	16	40%
		<i>A. m. mellifera</i>	4	10%
		<i>A. m. ligustica</i>	2	20%
<i>Apis mellifera mellifera</i>	10	<i>A. m. carnica</i>	2	20%
		<i>A. m. mellifera</i>	6	60%
		<i>A. m. carnica</i>	12	100%
Buckfast	12			

Conclusions

1. The honeybee population of Estonia includes individuals belonging to the three main mitochondrial lineages [17]:

C (91%); subspecies native to southern and eastern Europe
M (8%); subspecies native to western and northern Europe
A (1%); subspecies native to Africa and Iberian Peninsula.
2. The Estonian honeybee population is mostly (91%) comprised of two subspecies of the lineage C [1]:

Apis mellifera ligustica (55.1%): Italian honeybee; subspecies native to Italy
Apis mellifera carnica (35.9%): Carniolan honeybee; subspecies native to Slovenia, Bulgaria, Poland, Austria, Croatia, Bosnia and Herzegovina, Serbia, Hungary and Romania.
3. Only 7.7% of Estonian bees analysed here belong to the native *Apis mellifera mellifera* subspecies (European dark honeybee).
4. The haplotype diversity of the honeybee population in Estonia is comparable to that found in other world regions. For example, the number of different mtDNA haplotypes observed in Estonian bees (11 haplotypes in 156 sequences or 79 colonies) is within the range of what was observed in recent studies from other regions using the same mtDNA segment: Serbia (9 haplotypes in 241 samples) [24], USA (27 haplotypes in 1,063 samples) [4], Peru (24 haplotypes in 512 samples) [16], northern Poland, Hungary and Romania (45 haplotypes in 444 samples) [15] and 12 African countries (84 haplotypes in 1184 samples) [8].
5. Samples from *A. m. ligustica* belong to only two different haplotypes suggesting a low genetic diversity for individuals of this subspecies. This result can be explained either by the recurrent introduction of individuals from the same lineage or the local dispersion from a single early introduction in Estonia.
6. Samples from *A. m. carnica* showed a higher genetic diversity than *A. m. ligustica*, with seven different mtDNA haplotypes. This result suggest that multiple individuals of this species may have been introduced in Estonia.

7. Samples from *A. m. mellifera* are grouped into three different haplotypes found in three separated apiaries located in Harju County, Tartu maakond and Järva maakond. Considering that this subspecies is native to Estonia and that the apiaries are in different regions, it is possible that the individuals represent local native lineages that were collected by the beekeepers. Nevertheless, the independent introduction of *A. m. mellifera* from other regions of its natural distribution cannot be excluded with the present dataset.
8. The six cases of different mtDNA sequences between workers and drones of the same colony require further investigation. The cases with a few mutations of difference could be the result of new mutations within each individual, but the cases with several mutations could represent some sample processing error. The analysis of additional samples collected at the same time will clarify the situation.
9. There was a discordance in 46 % of samples between the classification of honeybees' subspecies by beekeepers and by the mtDNA analyses. The discordance can result from:
 - a) The existence of recent hybridization. Mitochondria are inherited exclusively from the female, meaning that only one parent's mitochondrial lineage is represented in the offspring. In hybridization events between two different subspecies, if the female belongs to one species and the male to another, the mtDNA of the hybrid will only reflect the maternal lineage. As a result, it may not accurately represent the genetic contribution of the other parent or the true hybrid nature of the individual.
 - b) The low genetic difference between *A. m. ligustica* and *A. m. carnica*. Since 30% of the samples with discordance in the classifications occurs between these species, it is possible that the similarity between the two species may lead to misclassifications using morphology alone.
10. All Buckfast honeybees had *A. m. carnica* maternal lineage, which is unexpected considering the origin of this breed using queens from Italy *A. m. ligustica* [25]. This result may suggest additional crossings in this Buckfast lineage.
11. Overall, the Estonian honeybee population is mainly comprised of commercial C-lineage honeybees. The native honeybee subspecies (*A. m. mellifera*) is rare,

despite representing a potential reservoir of unique combinations of genes adapted to local conditions. The level of genetic diversity is similar to other world regions, suggesting similar breeding practices.
